

How the wait after pricing is split

NAV Bottleneck report · Page 1 chart "Where funds waited after pricing arrived" · worked examples from the template's sample data, 31 Aug 2026

The **wait after pricing** is the time from when the pricing file **arrived** to when the maker marked the fund **Calculated**. The report cuts that one stretch of time into three parts. The three always add back to the total.

Queue: maker working on another fund Own recon: maker reconciling this fund

Other hold-up: everything else

Queue

Minutes when the **same maker was working on a different fund**.

Points to: capacity, workload, the order funds are picked up.

Own recon

Minutes the maker spent **reconciling this fund**, up to its recon budget.

Points to: expected work. Not a problem in itself.

Other hold-up

Everything else: the fund waited, but not for the maker's other work or its own recon.

Points to: data not ready, recon breaks, recon over budget, work not in the status log.

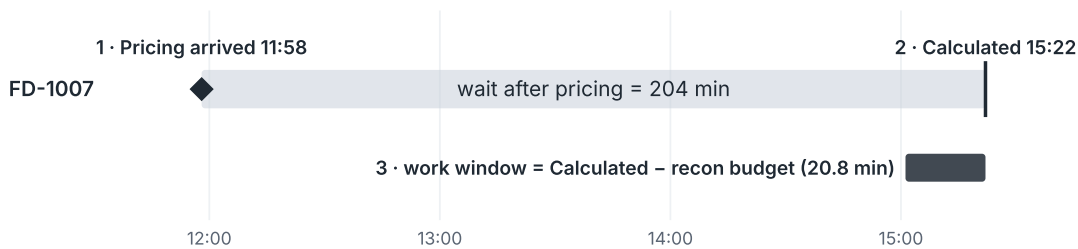

An everyday picture: a clinic

Report term	In a clinic	If this is large...
Fund · maker · pricing arrived	Patient · doctor · patient checks in	
Queue	The doctor is seeing other patients	...you need more doctors, or a better order
Own recon	The doctor is reading your file before calling you in	...that is normal preparation
Other hold-up	The doctor is free, but you still wait, for example for lab results	...fix the lab, not the doctor's diary

Why not call it "idle"? The same maker usually does both the reconciliation and the calculation. Time spent reconciling the fund is work, so it gets its own colour. Only what is left after queue and own recon is called other hold-up.

Step 1 · Three ingredients for every fund-day

Everything comes from data the template already holds. Nothing extra is captured.

- 1 Pricing arrived:** when the TOP pricing file landed (Fact_Milestone, looked up into Fact_Work column U).
- 2 Calculated:** when the maker set the fund to "Calculated" in the status log (Fact_Work column W, the NAV start).
- 3 Work window:** no system records when someone *starts* a fund, so the template estimates it as **Calculated minus the fund's recon budget** (Recon_Mins, from the weightage). For FD-1007 that is $15:22 - 20.8 \text{ min} = 15:01$. These are Fact_Work columns BS (start) and BT (end).

Step 2 · Fill three buckets, in this order

#	Bucket	Rule
1	 Queue	Look at the same maker's other fund-days on the same processing date . Add up every minute where their work window overlaps this fund's wait. Never more than the total wait.
2	 Own recon	From what is left, take up to this fund's recon budget .
3	 Other hold-up	Whatever is left: wait – queue – own recon.

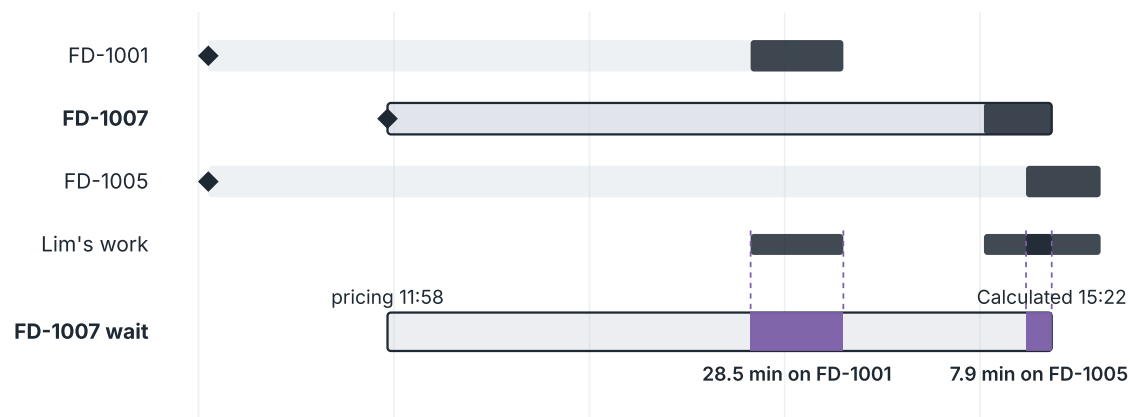

Because bucket 3 takes the remainder, the three parts always add up to the wait exactly. The Checks sheet line *"Wait split does not add up"* must read 0.

Why only overlaps, not "until the maker's previous fund finished"? If the fund ahead was itself stuck (say, waiting for data), the maker was not actually busy, and that stuck time should not be blamed on capacity. Counting only the minutes inside other funds' work windows stops one fund's hold-up being passed down the line as "queue".

Worked example · FD-1007, maker Lim Wei Ming, 31 Aug

Lim calculated three funds that day. Each row shows the fund waiting (grey, from its pricing diamond to its Calculated time) and its work window (dark). The bottom row is FD-1007's wait; the purple slices are the minutes Lim's work on the other two funds falls inside it.

- pricing arrived fund waiting (pricing arrived → Calculated)
- work window (recon budget before Calculated) overlap = queue minutes

Step	Working	Minutes
Total wait	Pricing arrived 11:58 → Calculated 15:22	204
Queue	FD-1001 work window 13:49:30–14:18 lies fully inside the wait: 28.5 min. FD-1005 work window 15:14:06–15:37 overlaps the wait until 15:22: 7.9 min. 28.5 + 7.9 = 36.4, rounded	36
Own recon	FD-1007 recon budget is 20.8 min. 204 – 36 = 168 min is left, so the full budget fits. Rounded	21
Other hold-up	204 – 36 – 21	147

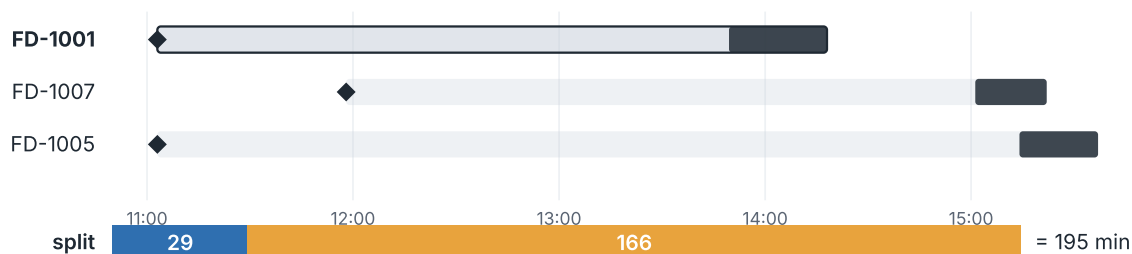

How to read it. For about 2½ hours of FD-1007's wait, Lim was not recorded working on another fund and the fund's own recon budget only explains 21 minutes. That 147 minutes is what to investigate: was data late, was there a recon break, or does the recon really take far longer than its budget?

The own-recon minutes are an amount, not a place on the clock: they are taken from whatever time is left after the queue. That is why the split bar is drawn separately from the timeline.

Three more situations

- ◆ pricing arrived ■ fund waiting (pricing arrived → Calculated)
- work window (recon budget before Calculated) ■ overlap = queue minutes

A · First fund of the day, mostly other hold-up (FD-1001, Lim, 31 Aug)

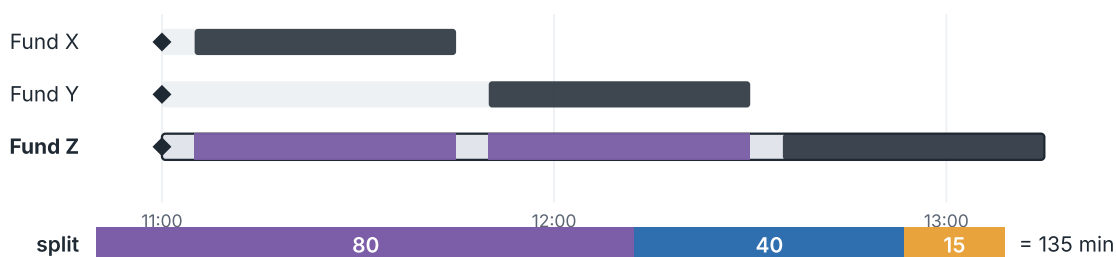

Pricing arrived 11:03, Calculated 14:18: a 195-minute wait. Lim's other work windows that day (FD-1007, FD-1005) are all **after** 14:18, so nothing overlaps: **queue 0**. Own recon takes its full budget of 28.5 → **29**. The remaining **166 minutes** are other hold-up, the strongest signal on the day that something other than workload held this fund.

B · Short wait, recon capped (FD-1003, Chen Xiao, 31 Aug)

Pricing arrived 11:58 and Chen calculated at 12:10: only **12 minutes** of wait. The recon budget is 27.5 minutes, but only 12 minutes of wait exist, so own recon is **capped at 12** and other hold-up is **0**. Much of the recon happened before pricing even arrived, which is the healthy pattern.

C · A real capacity problem (made-up example, for illustration)

Pricing for three funds lands at 11:00 and one maker works them back to back. Fund Z waits 135 minutes (11:00 → 13:15). Its wait overlaps Fund X's work window (40 min) and Fund Y's (40 min): **queue 80**. Own recon takes its 40-minute budget, and only **15 minutes** are other hold-up. Mostly purple means the fix is capacity or a better pick-up order, not the data.

Your sample data has no day like C: across it, queue is about 5% of the wait, own recon 12% and other hold-up 83%.

Reading the chart, and what to do

If the bar is mostly...	It means	Look at
 Purple (queue)	Funds waited while their maker was busy on other funds.	Workload per analyst, reassignment, the order funds are picked up, month-end peaks.
 Blue (own recon)	Funds were being reconciled after pricing arrived.	Whether more recon could be done before pricing lands.
 Amber (other hold-up)	Funds waited for something other than the maker's work.	Late data, recon breaks, recon budgets that are too low, work outside the status log.

The chart groups fund-days four ways: broker-dependent or not, and thin or ample custody slack. A fund-day sits in one broker group *and* one custody group, so the groups overlap. If one group carries much more amber than its partner, that dependency is the likely hold-up.

Where each number lives in the workbook

Fact_Work column	What it holds
AC · Wait_After_Pricing_Mins	Calculated – pricing arrival, never below 0
BS · Work_Start_Num BT · Work_End_Num	Each fund-day's work window: Calculated – recon budget, to Calculated
BD · Queue_Wait_Mins	Overlap of this fund's wait with the same maker's other work windows, same processing date, capped at the wait
BE · Own_Recon_Mins	The smaller of (wait – queue) and the recon budget
BR · Other_Holdup_Mins	Wait – queue – own recon

In Power BI: **[Avg Queue Wait]**, **[Avg Own Recon Wait]**, **[Avg Other Holdup Wait]** on the chart; **[Queue Share of Wait]**, **[Own Recon Share of Wait]** and **[Other Holdup Share of Wait]** for cards. The three shares add to 100%.

What this can and cannot claim

- **Reconstructed, not observed.** Work windows are estimated from recon budgets, because no system records when work starts.
- Recon that runs **over** its budget shows up as other hold-up. A fund that is always amber may simply have a budget that is too low.
- Only work in the **status log** counts. Meetings, queries and non-NAV tasks are invisible and land in other hold-up.
- Estimated work windows can overlap one another. Queue is counted first; own recon comes from what is left.

One line for the textbox: Waiting: purple is queueing behind other funds, blue is the maker reconciling this fund, amber is any other hold-up such as data or breaks.
